The largest uncertainty in determining orbits for satellites operating in low Earth orbit is the atmospheric drag. Drag is the most difficult force to model mainly because of the complexity of neutral atmosphere variations driven by the Sun, and the propagation from below of lower atmosphere waves [5, 6].

Generally when determining trajectories, it may be necessary to account for nonuniform gravitational forces and air resistance (drag and aerodynamics). This is the focus of the discipline of ballistics. One of the remarkable achievements of Newtonian mechanics was the derivation of the laws of Kepler.

The way the flow is currently built, it looks for a matching contact record before determining whether to update the existing one or create a new one. That's a wasted data element: Why look up the ID of a matching record if the user opts to create a new contact anyway? To fix that, let's break the existing decision into two decisions.
